#### 1 Overview

Supplementary materials for, "Consonant Stability in Portuguese-based creoles", by Carlos Silva and Steven Moran, to appear in Diachronica.

These supplementary materials are available online at:

 $\bullet \ \, https://github.com/CreoPhon/consonant\_stability\_portuguese\_creoles$ 

In this report, we provide code in R (R Core Team 2023) and we use these R libraries (Wickham et al. 2019; Xie 2021; Slowikowski 2022; Kuznetsova, Brockhoff, and Christensen 2017; Wood 2004; Pohlert 2023; Kassambara 2023a, 2023b; Hennig and Hausdorf 2023; Becker et al. 2023):

```
library(tidyverse)
library(knitr)
library(ggrepel)
library(lmerTest)
library(mgcv)
library(PMCMRplus)
library(ggpubr)
library(rstatix)
```

```
library(stats)
library(prabclus)
library(maps)
# Set the theme for all figures
theme_set(theme_bw())
Load the data set.
database <- read_csv("database.csv")</pre>
We extend the database with some additional variables. First, duration of contact.
database$duration <- database$`EndOfInfluence` - database$`FirstMajorSettlement`</pre>
Next, a variable of global stability.
database <- mutate(database, GlobalStability = (PlaceStability + MannerStability) / 2)</pre>
Also, a categorical variable for duration.
database <- database %>%
  mutate(duration_group = ifelse(duration <= 250, "short", "long"))</pre>
And a categorical variable for changes in manner and/or place. Stability in the database is '1' (no change)
and '0' (change).
database <- database %>%
  mutate(categorical_stability = ifelse(PlaceStability == 1 & MannerStability == 1,
                                           "no manner/no place", NA))
database <- database %>%
  mutate(categorical_stability = ifelse(PlaceStability == 1 & MannerStability == 0,
                                           "manner/no place", categorical_stability))
database <- database %>%
  mutate(categorical_stability = ifelse(PlaceStability == 0 & MannerStability == 1,
                                           "no manner/place", categorical stability))
database <- database %>%
  mutate(categorical_stability = ifelse(PlaceStability == 0 & MannerStability == 0,
                                           "manner/place", categorical_stability))
table(database$categorical_stability)
##
##
      manner/no place
                             manner/place no manner/no place
                                                                   no manner/place
```

## 2 Language sample

##

Here are the languages plotted on a world map.

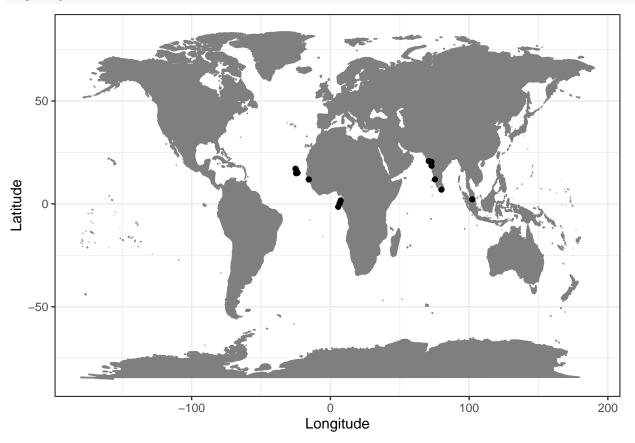

```
locations <- read_csv('creole_locations.csv')

ggplot(data = locations, aes(x = Longitude, y = Latitude)) +
  borders("world", colour="gray50", fill="gray50") +</pre>
```

553

58

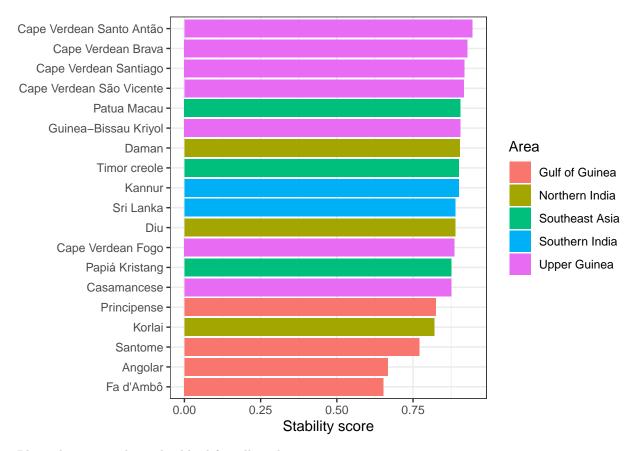

# 3 Creole stability

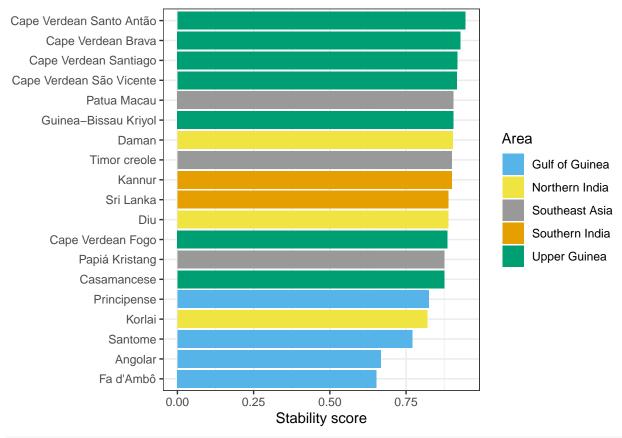

Which creoles in the sample are more or less stable overall?

```
creole_stability <- database %>%
  group_by(Language, Area, duration, duration_group, ContactConditions) %>%
  summarize(MeanStability = mean(GlobalStability, na.rm = TRUE))
write_csv(creole_stability, 'creole_stability.csv')
```

Plot it by area.

Plot it by area with a color-blind friendly palette.

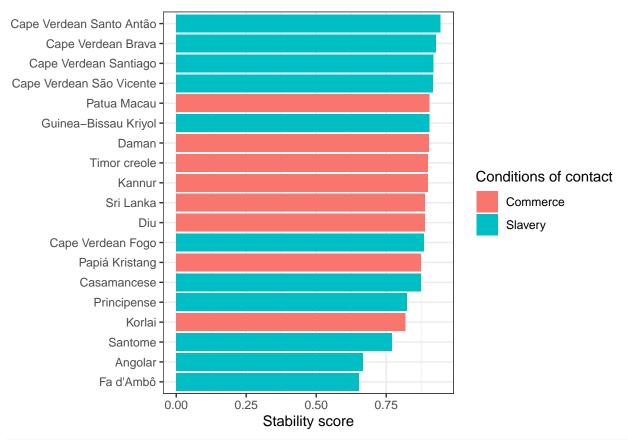

```
table(creole_stability$Area)
```

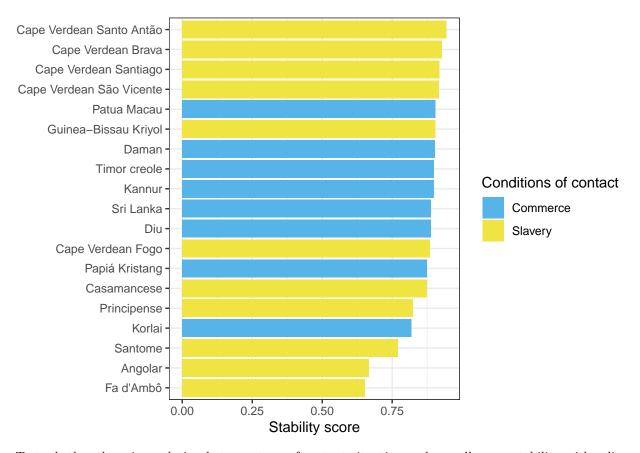

```
## ## Gulf of Guinea Northern India Southeast Asia Southern India Upper Guinea ## 4 3 3 2 7
```

#### 3.1 Conditions of contact

We have the overall stability values. What are these in relation to the conditions of contact?

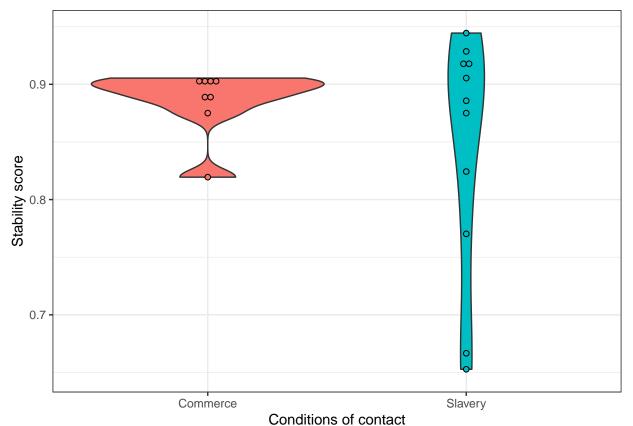

The finding that "slavery has a negative impact on stability" was mainly observational (e.g. Faraclas et al. (2007); Carvalho and Lucchesi (2016)). Upper Guinea are considered "light" creoles, i.e., enslaved people with "lighter" contact conditions. Gulf of Guinea are considered "hard" creole, i.e., enslaved people under "harder" contact conditions.

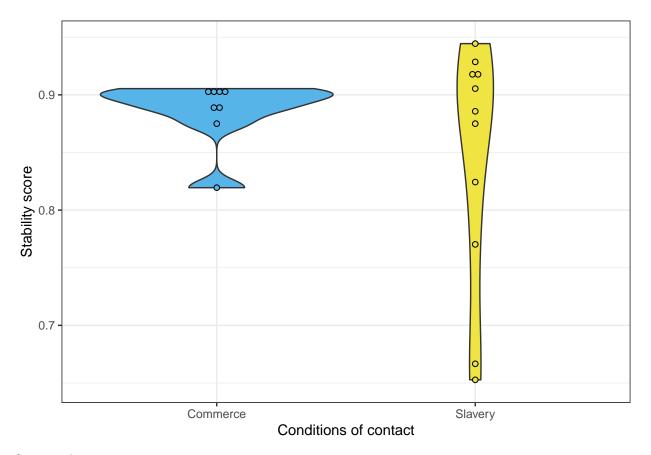

Test whether there is a relation between type of contact situation and overall mean stability with a linear model.

```

```

## `geom\_smooth()` using formula = 'y ~ x'

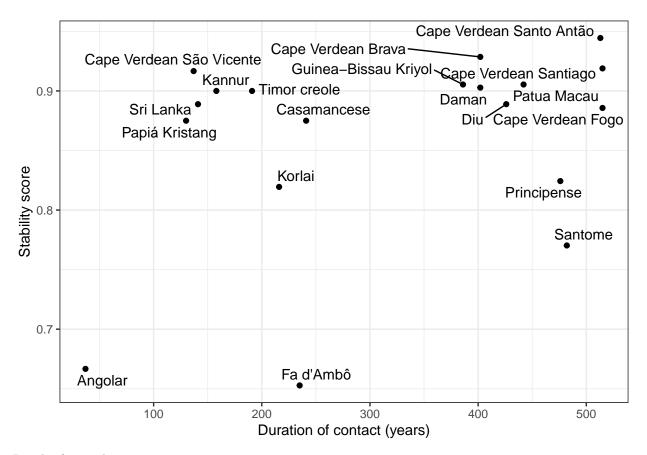

### 3.2 Duration of contact

We have the overall stability values. What are these in relation to the duration of contact?

There does not seem to be a relationship between overall duration and overall stability.

```
ggplot(creole_stability, aes(x = duration, y = MeanStability)) +
  geom_point() +
  geom_text_repel(aes(label = creole_stability$Language)) +
  xlab("Duration of contact (years)") +
  ylab("Stability score")
```

Results from a linear regression.

```
msd <- lm(MeanStability ~ duration, data = creole_stability)
summary(msd)</pre>
```

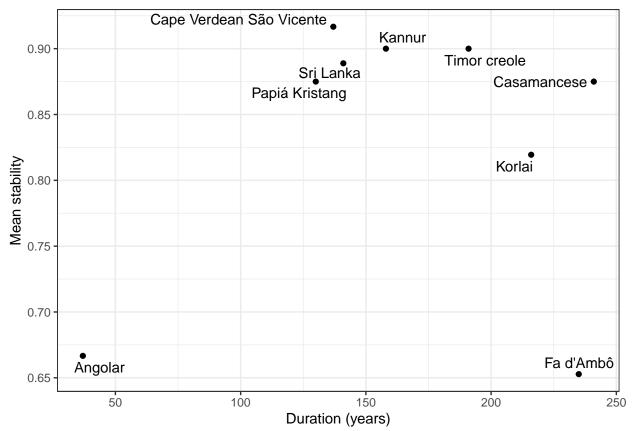

```
##
## Call:
## lm(formula = MeanStability ~ duration, data = creole_stability)
##

```

However, there does seem to be two groups of languages – ones that belong to "long duration" (>= 400 years) and those that belong to "short duration" (<= 250 years).

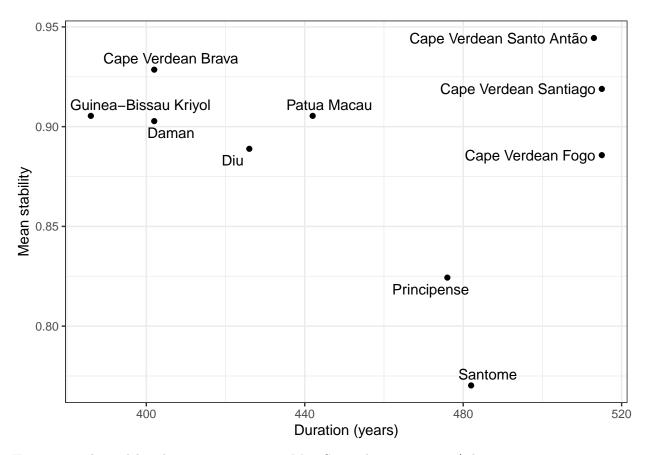

We split the data and rerun the models, but we note that there are very few data points.

```
tmp_short <- creole_stability %>% filter(duration <= 250)
tmp_long <- creole_stability %>% filter(duration > 250)

ggplot(tmp_short, aes(x = duration, y = MeanStability)) +
    geom_point() +
    geom_text_repel(aes(label = tmp_short$Language)) +
    xlab("Duration (years)") +
    ylab("Mean stability")
```

```
ggplot(tmp_long, aes(x = duration, y = MeanStability)) +
geom_point() +
geom_text_repel(aes(label = tmp_long$Language)) +
xlab("Duration (years)") +
ylab("Mean stability")
```

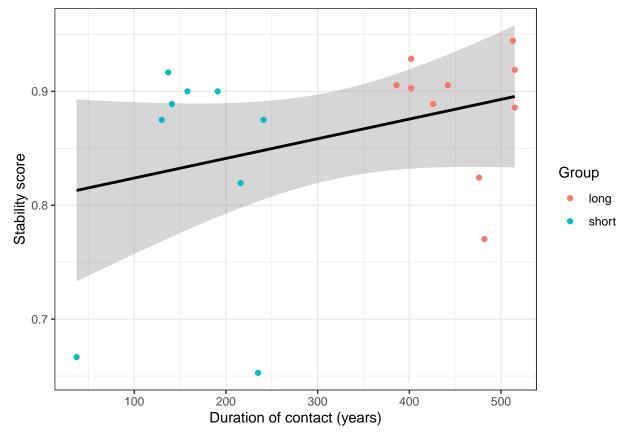

Here is a single model with an interaction term MeanSim ~ duration, group \* duration.

```
msd <- lm(MeanStability ~ duration + duration_group * duration, data = creole_stability)
summary(msd)</pre>
```

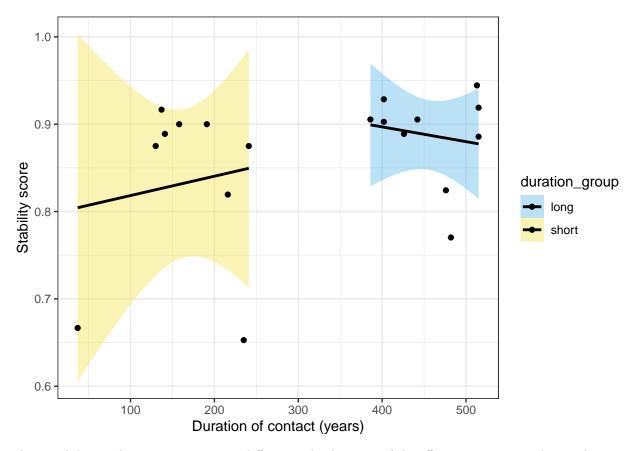

```

## `geom\_smooth()` using formula = 'y ~ x'

The variability in the two groups is very different. The direction of the effect is interesting: shorter durations yield more stability more consistently. Over time, the variability in mean stability increases. Time is "destabilizing the pattern of stability" (pc Nicholas Lester).

And we can also increase the number of observations by running the analysis at the segment level, rather than on mean stability.

Here is an exploratory analysis with a generalized additive model (GAM).

## MeanStability ~ duration\_group + s(duration, k = 3) + s(duration,

by = duration\_group, k = 3)

## Main effect of duration

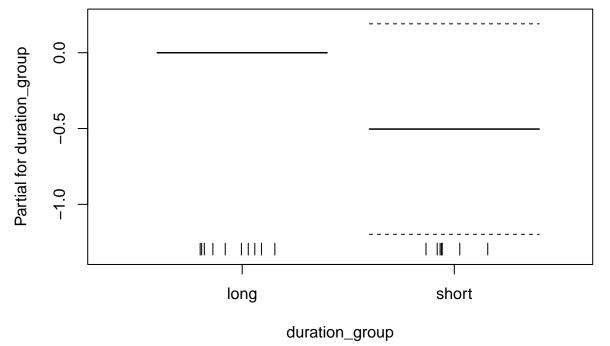

# Long-term influence

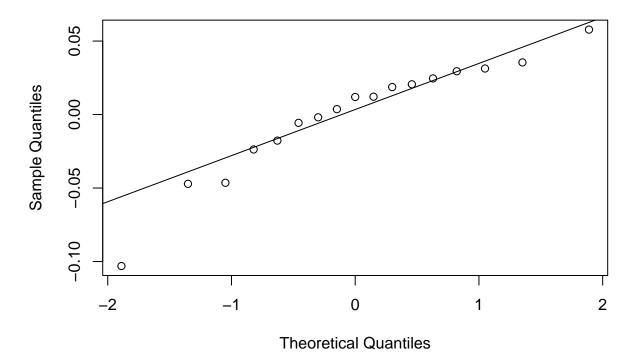

## Short-term influence

```
# checking out the model performance
qqnorm(resid(msd.gam.trimmed))
qqline(resid(msd.gam.trimmed)) # meh
```

# Normal Q-Q Plot

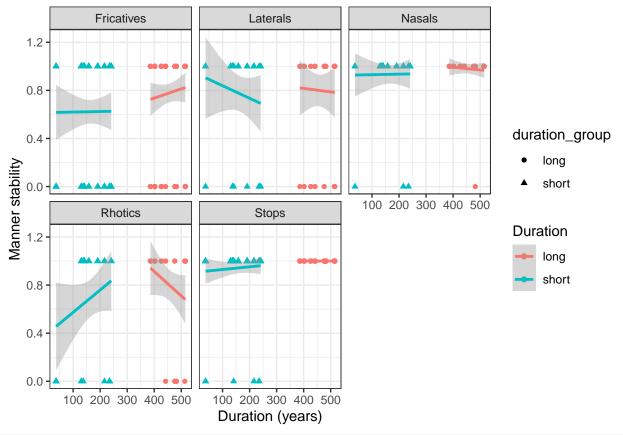

Removing the two creoles with the lowest scores produces significant effects. This does not seem very reliable though, especially given the small sample size. Also, the pattern is strange: a negative trend of duration for long-term influence and a positive one for short-term influence? Note that the model detected a mean difference between duration groups, with the short group having (slightly) lower mean stability. This appears to be the case – but again – there are very few observations.

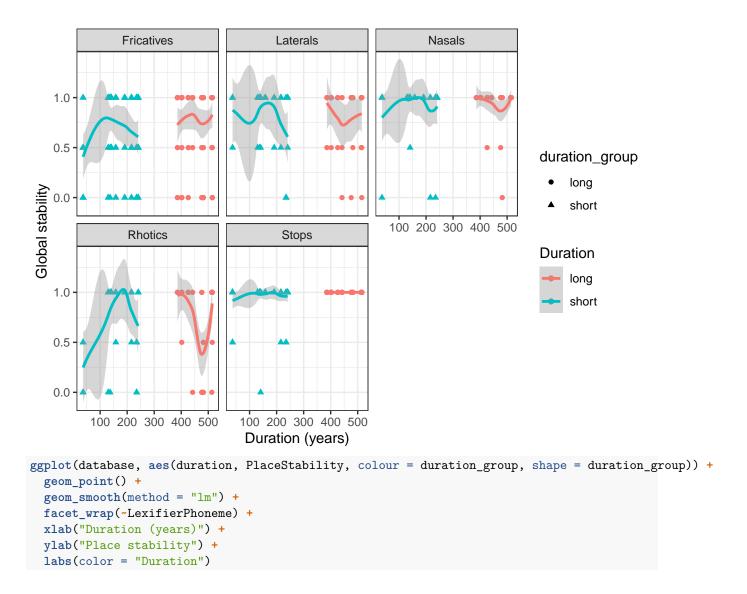

#### 3.3 Duration effects on the segment level

Does duration affect the stability values of specific segments or segment classes?

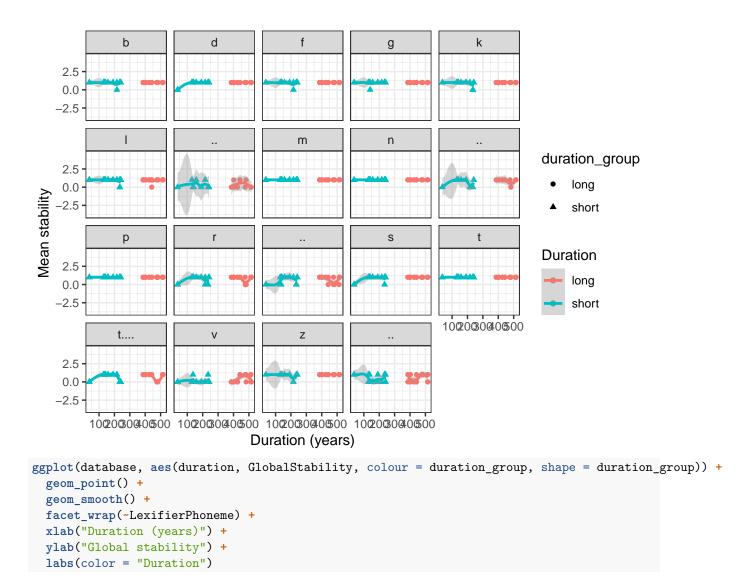

```
ggplot(database, aes(duration, MannerStability, colour = duration_group, shape = duration_group)) +
  geom_point() +
  geom_smooth(method = "lm") +
  facet_wrap(~Class) +
   xlab("Duration (years)") +
  ylab("Manner stability") +
  labs(color = "Duration")
```

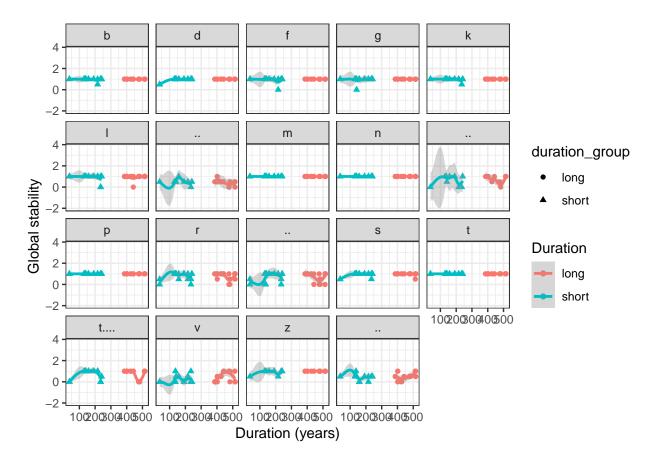

```
ggplot(database, aes(duration, GlobalStability, colour = duration_group, shape = duration_group)) +
  geom_point() +
  geom_smooth() +
  facet_wrap(~Class) +
    xlab("Duration (years)") +
    ylab("Global stability") +
  labs(color = "Duration")
```

#### 3.4 Jaccard distance between inventories

Here we explore the Jaccard distance between phonological inventories.

```
df_jac <- read_csv("Inventories.csv")</pre>
#df_jac <- df_jac %>% subset(Category != 'creole')
df_jac <- df_jac %>% dplyr::select(c('Language','Phoneme'))
df_jac$presence <- 1</pre>
df_wide <- df_jac %>% spread(Phoneme, presence)
df_wide <- df_wide %>% replace(is.na(.), 0)
head(df_wide)
## # A tibble: 6 x 116
                                                                                                                                                                                                                                                                                                       `b`
##
                                                                                                                                                        b
                                                                                                                                                                                       `b`

The Jaccard distance values were manually extracted into a new table, so we could visualize those values according to the relevant language in contact (see file <code>jaccard\_results.csv</code>). Then, we created a new table which summaries those results for creoles and joins their stability values, so we can assess if there is or if there is not a correlation between the Jaccard distances and the overall stability os creoles.

```
df_cor <- read.csv("jaccard_summary.csv")</pre>
```

We create a linear model of inventory distance creoles ~ Portuguese.

```
cl <- lm(stability ~ lex_crio, data=df_cor)
summary(cl)</pre>
```

```

## 4 Consonant stability

Which segments are the most stable across creoles in the language sample? We calculate stability of place and manner for each phoneme.

```
consonant_stability_class <- cbind(consonant_stability, class)</pre>
```

Next, we plot the results.

```
ggplot(consonant_stability, aes(y = mmanner, x = mplace)) +
geom_point(position = "dodge", aes(color = class)) +
geom_text_repel(aes(label = LexifierPhoneme), size = 4) +
xlab("Mean stability (place of articulation)") +
ylab("Mean stability (manner of articulation)") +
labs(color = "Segment class")
```

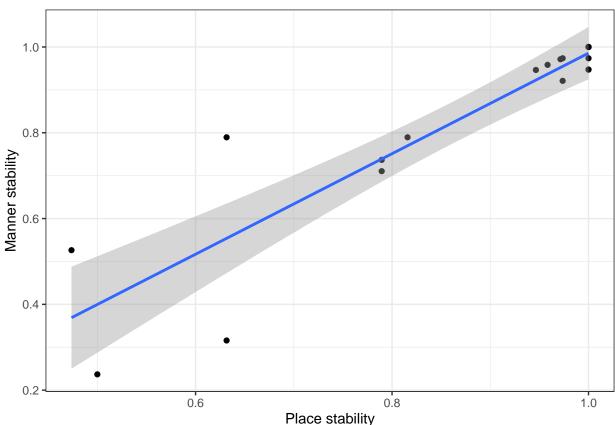

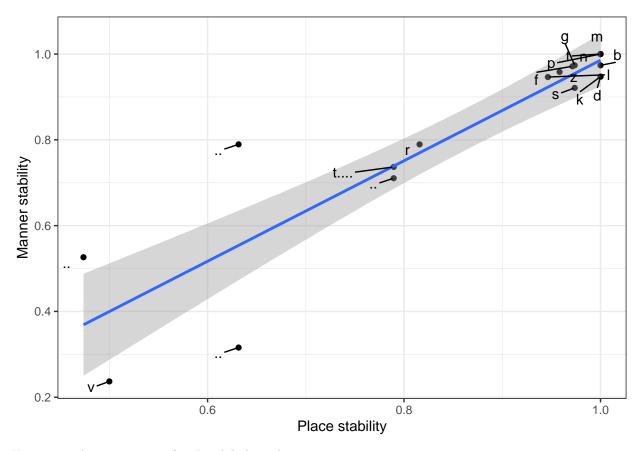

We make a linear model to assess the relationship between manner and place stability.

```
lm_manner_place <- lm(mplace~mmanner, data=consonant_stability)
summary(lm_manner_place)</pre>
```

### 4.1 Manner stability

Check for class effects on the global stability of consonants.

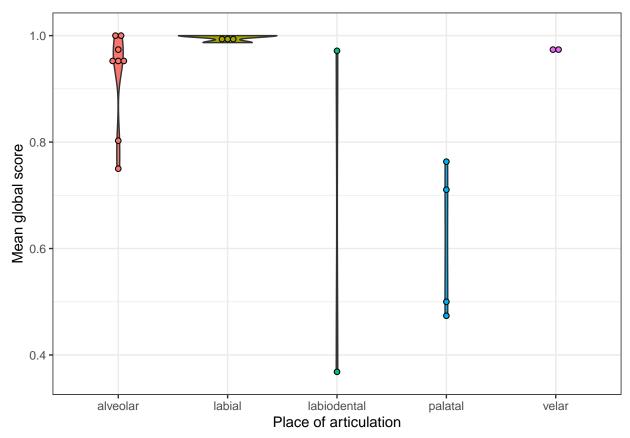

Now, just plotting the relation manner to manner.

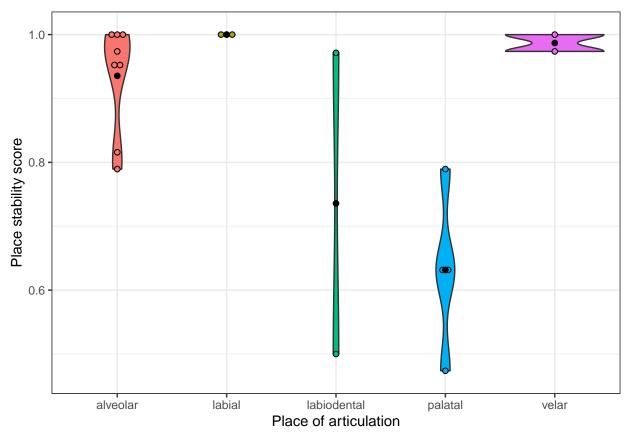

### 4.2 Place stability

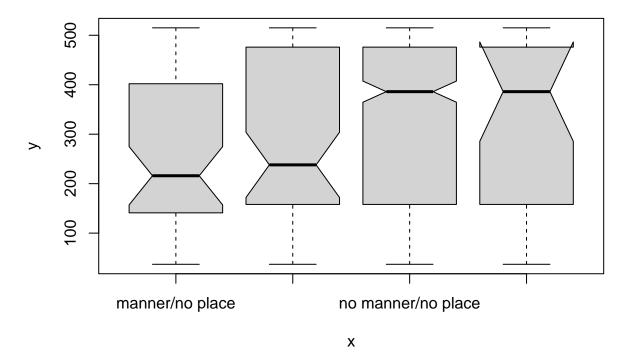

We check place effects on the global stability of the consonants.

Now, just with the mean for place stability.

We can also increase the number of observations in duration regression by running the analysis at the segment level, rather than on mean stability.

Hugely skewed in favor of no manner/place (10x as frequent as the next most frequent level; note this may cause problems for the models).

```

```

There is some indication that place stability is more often associated with shorter periods of influence.

Numerically, the manner/place category has 50% of its observations in the longest duration from the sample. At the same time, no manner/no place is associated with the shortest duration.

### 4.3 Word position

Next we ask, does word position influence stability?

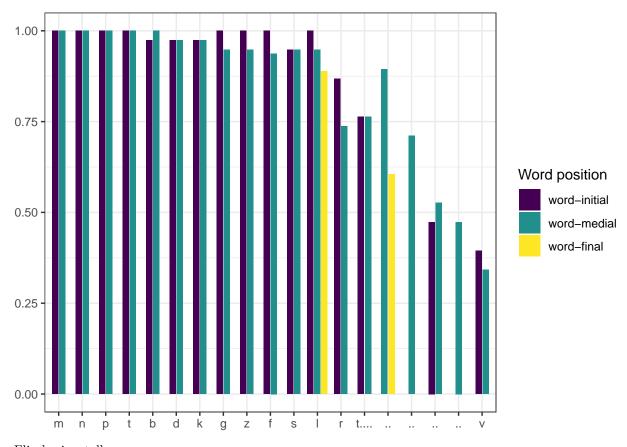

First, data preparation.

```
data_by_position <- database %>%
    dplyr::select(Position, LexifierPhoneme, PlaceStability, MannerStability) %>%
```

```
mutate(Position = tolower(Position))
data_by_position$PlaceStability <- as.numeric(data_by_position$PlaceStability)
data_by_position$MannerStability <- as.numeric(data_by_position$MannerStability)</pre>
```

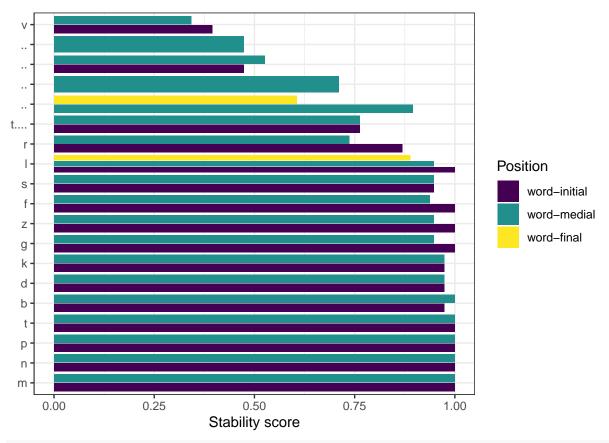

Next, calculate stability for each segment according to its word position.

And plot the results for all segments.

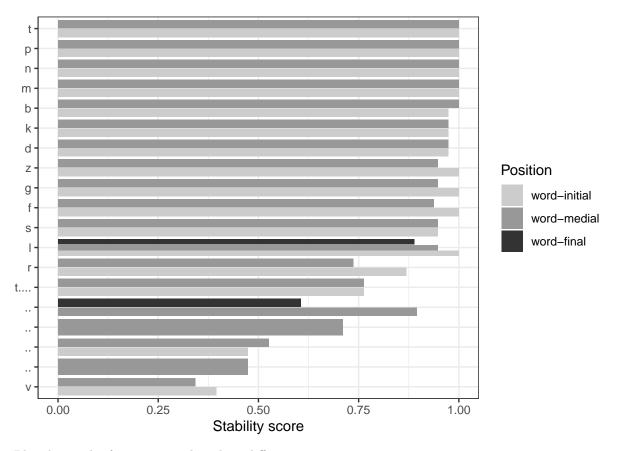

Flip horizontally.

```
ggplot(position_results) +
  geom_bar(
  aes(
    x = m,
    y = reorder(LexifierPhoneme, -m),
    # y = LexifierPhoneme,
    fill = Position
  ),
  stat = "identity",
  show.legend = TRUE,
  position = "dodge2"
  ) +
  labs(x = "Stability score", y = "", fill = "Position")
```

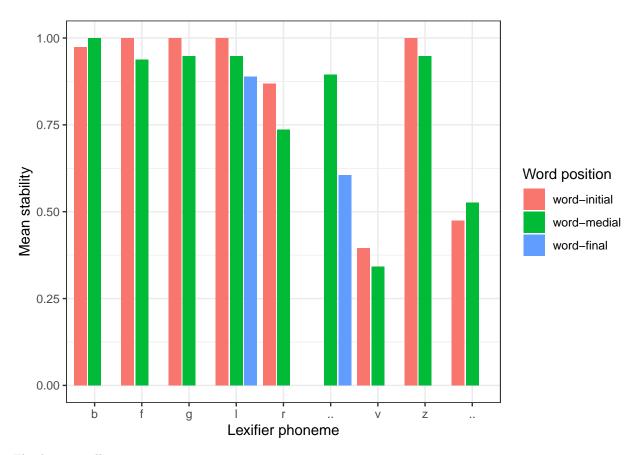

```
ggplot(position_results) +
  geom_bar(
    aes(
        x = m,
        y = reorder(LexifierPhoneme, m),
        fill = Position
    ),
    stat = "identity",
    show.legend = TRUE,
    position = "dodge2"
) +
  labs(x = "Stability score", y = "", fill = "Position") +
  scale_fill_grey(start = 0.8, end = 0.2)
```

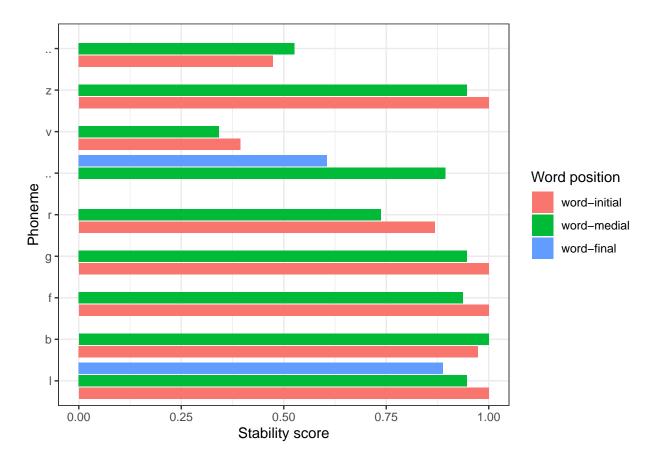

Plot the results for segments that show differences.

```
position_results1 <- position_results %>%
  pivot_wider(names_from = Position, values_from = m)
different_position <- subset(position_results1, position_results1$`word-initial`</pre>
                             != position_results1$`word-medial` |
                               position_results1$`word-final`
                             != position_results1$`word-medial`)
different_position_results <- different_position %>%
 pivot_longer(c(`word-initial`, `word-medial`, `word-final`),
               names_to = "Position", values_to = "m")
different_position_results$Position <- factor(different_position_results$Position,
                                              levels = c("word-initial",
                                                          "word-medial",
                                                          "word-final"))
ggplot(
  different_position_results,
  aes(x = LexifierPhoneme, y = m, fill = Position)
  geom_col(position = position_dodge2(width = 0.9, preserve = "single")) +
 labs(x = "Lexifier phoneme", y = "Mean stability", fill = "Word position")
```

Flip horizontally.

```
ggplot(different_position_results) +
  geom_bar(
    aes(
        x = m,
        y = reorder(LexifierPhoneme, m),
        fill = Position
    ),
    stat = "identity",
    show.legend = TRUE,
    position = "dodge2"
    ) +
    labs(x = "Stability score", y = "Phoneme", fill = "Word position")
```

## 4.4 Typological frequency and borrowability

First, we turn the data into ordinal values. Ordinal data was generated by ranking the percentage values of stability, borrowability and typological frequency from 1 to 19. Duplicate values summed and averaged in the ranking.

Cross linguistic frequency

2) Borrowability

3) Stability values

Then, we create the data frames and prepare them for non-parametric tests. Long format with joint groups.

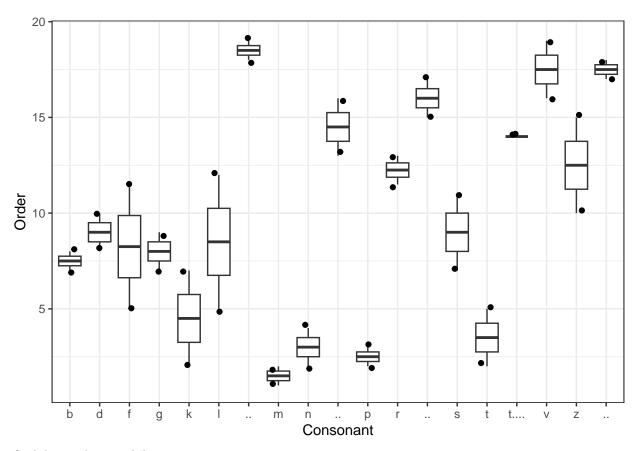

```
df_friedman <- left_join(df_sta, df_bor, by="consonant")</pre>
order_df <- left_join(df_friedman, df_typ, by="consonant")</pre>
head(order_df)

```

There is a relationship between stability and frequency across all languages in the sample. But does it make sense? We are measuring the consonants in all categories and the present of the lexifier and the creoles may influence the results. Thus, we subset and measure the frequency across substrates only, but this procedure may just increase the lack of correlation.

Is there a relationship between consonant stability and their presence in the inventories of the substrate languages?

Data preparation (substrates only).

```
inv_subs <- inv %>% subset(Category == 'substrate') %>%
    dplyr::select(Language, Phoneme) %>%
    mutate(newcol = 1)

inv_subs_long <- inv_subs %>%
    pivot_wider(names_from = Language, values_from = newcol, values_fill = 0)

inv_subs_long <- inv_subs_long %>%
    mutate_at(c(2:18), as.numeric)

head(inv_subs_long)

##
## Residual standard error: 0.2672 on 16 degrees of freedom
     (1 observation deleted due to missingness)
## Multiple R-squared: 0.4105, Adjusted R-squared: 0.3736
## F-statistic: 11.14 on 1 and 16 DF, p-value: 0.004175
Plot the results.
```

```
subsfreq_sta_cor <- ggplot(subs_sta, aes(x = frequency, y = mglobal, label = LexifierPhoneme)) +
   geom_smooth(method = "lm", colour="black") +
   geom_point() +
   xlab("Frequency across substrates") + ylab("Stability across creoles") # +
   # geom_text(aes(label=V1), hjust=3, vjust=0)</pre>
subsfreq_sta_cor + geom_text_repel(aes(label=LexifierPhoneme))
```

When we consider the correlation between the consonant stability in creoles and the frequency of these consonants in the substrates only, we find that there is a weaker correlation (if we compare with the results above). However, this correlation is statistically significant (p-value: 0.004). Nothing the outliers which are normally voiced consonants.

Typological frequency vs. Substrate frequency.

Typological frequency data, extrated from PHOIBLE.

```
typ_freq <- read.csv("typ_freq.csv")</pre>
```

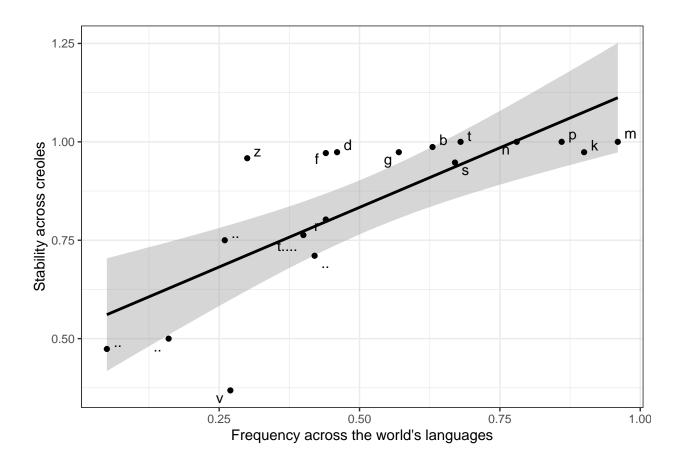

Merge the datasets.

```
#consonant_global_stability <- read.csv("consonant_global_stability.csv")
typ_sta <- left_join(typ_freq, consonant_global_stability, by='LexifierPhoneme')</pre>
```

Results of a linear regression.

```
typ_sta_lm <- lm(TypologicalFreq ~ mglobal, data=typ_sta)
summary(typ_sta_lm)</pre>
```
