1 Overview

Supplementary materials for, "Consonant Stability in Portuguese-based creoles". In this report, we provide code in R (RStudio Team 2020) and we use these R libraries (Wickham et al. 2019; Xie 2021; Slowikowski 2022; Kuznetsova, Brockhoff, and Christensen 2017; Wood 2004):

```
library(tidyverse)
library(knitr)
library(ggrepel)
library(lmerTest)
library(mgcv)
library(PMCMRplus)
library(ggpubr)
```

Warning: package 'ggpubr' was built under R version 4.3.1

```
library(rstatix)
library(stats)
library(prabclus)
```

```
## Warning: package 'prabclus' was built under R version 4.3.1
```

Warning: package 'mclust' was built under R version 4.3.1

```
# Set the theme for all figures
theme_set(theme_bw())
```

Load the data set.

```
database <- read_csv("database.csv")</pre>
```

The data look like this:

```
database %>%
 head() %>%
kable()
```

We extend the database with some additional variables. First, duration of contact.

```
database$duration <- database$`EndOfInfluence` - database$`FirstMajorSettlement`</pre>
```

Next, a variable of global stability.

```
database <- mutate(database, GlobalStability = (PlaceStability + MannerStability) / 2)</pre>
```

Also, a categorical variable for duration.

```
database <- database %>%
  mutate(duration_group = ifelse(duration <= 250, "short", "long"))</pre>
```

And a categorical variable for changes in manner and/or place. Stability in the database is '1' (no change) and '0' (change).

```
##
## manner/no place manner/place no manner/no place no manner/place
## 49 58 553 25
```

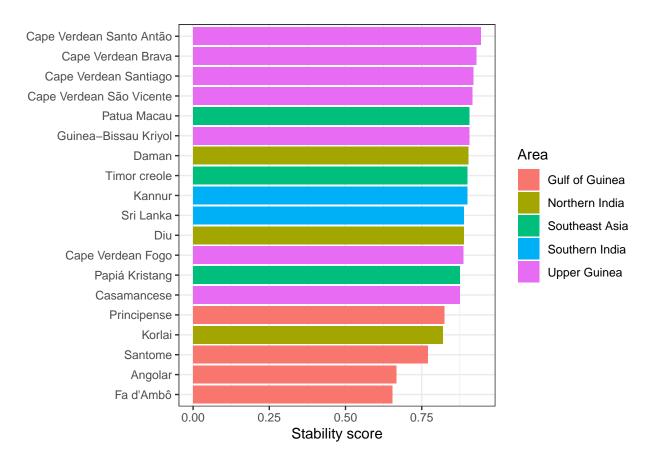

2 Creole stability

Which creoles in the sample are more or less stable overall?

```
creole_stability <- database %>%
  group_by(Language, Area, duration, duration_group, ContactConditions) %>%
  summarize(MeanStability = mean(GlobalStability, na.rm = TRUE))
write_csv(creole_stability, 'creole_stability.csv')
```

Plot it by area.

```
ggplot(creole_stability) +
  geom_bar(aes(x = MeanStability, y = reorder(Language, MeanStability), fill = Area), stat = "identity"
  theme(axis.title.y = element_blank()) +
  labs(x = "Stability score")
```

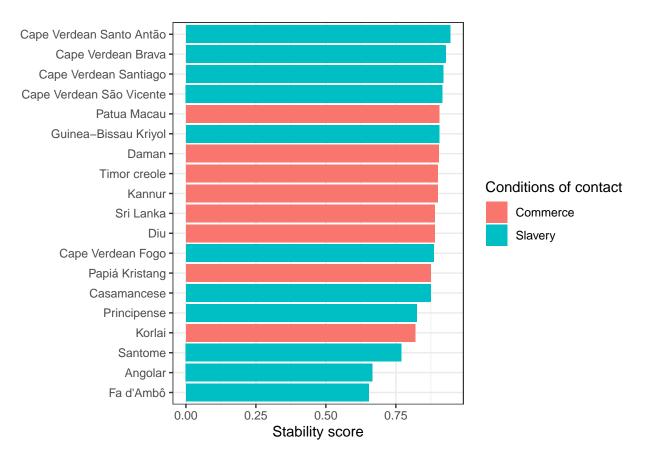

```
table(creole_stability$Area)
```

```
##
## Gulf of Guinea Northern India Southeast Asia Southern India Upper Guinea
## 4 3 3 2 7
```

2.1 Conditions of contact

We have the overall stability values. What are these in relation to the conditions of contact?

The finding that "slavery has a negative impact on stability" was mainly observational and also literature-based (e.g. Faraclas et al. (2007); Carvalho and Lucchesi (2016); Upper Guinea light creoles = slavery but with lighter contact conditions versus Gulf of Guinea hard creole = slavery and harder contact conditions).

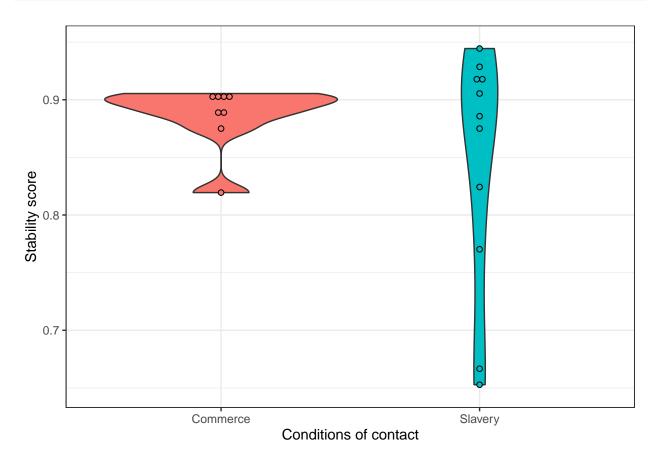

Test whether there's a relation between type of contact situation and overall mean stability.

Linear model

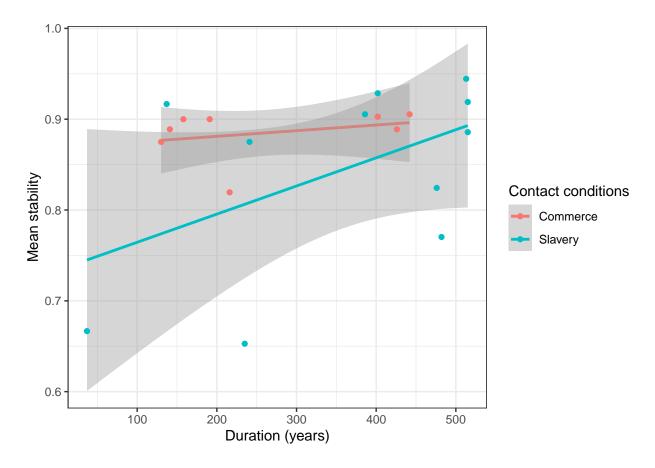

```
m <- lm(MeanStability ~ ContactConditions, data = creole_stability)
summary(m)</pre>
```

```

2.2 Duration of contact

We have the overall stability values. What are these in relation to the duration of contact? There does not seem to be a relationship between overall duration and overall stability.

```
ggplot(creole_stability, aes(x = duration, y = MeanStability)) +
geom_point() +
xlab("Duration (years)") +
ylab("Mean stability")
```

```
ggplot(creole_stability, aes(x = duration, y = MeanStability)) +
  geom_point() +
  geom_text_repel(aes(label = creole_stability$Language)) +
  xlab("Duration of contact (years)") +
  ylab("Stability score")
```

Results from the simple regression.

```
msd <- lm(MeanStability ~ duration, data = creole_stability)
summary(msd)</pre>
```

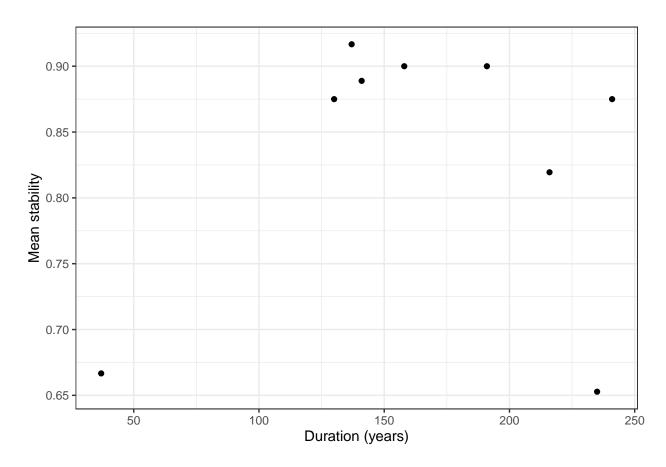

```
##
## lm(formula = MeanStability ~ duration, data = creole_stability)
##
## Residuals:

```

However, there does seem to be two groups of languages – ones that belong to "long duration" (>= 400 years) and those that below to "short duration" (<= 250 years).

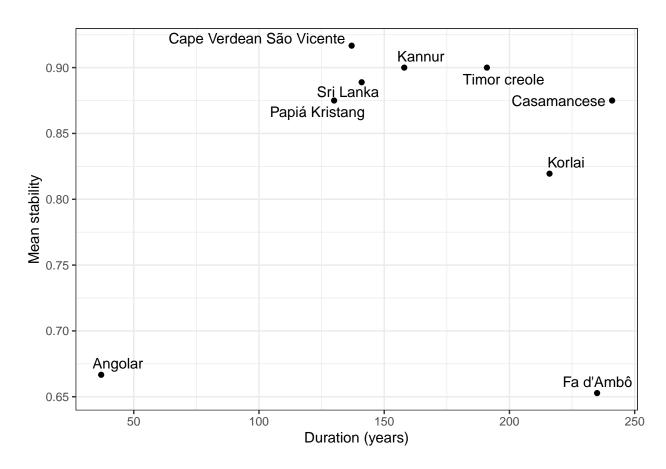

We can try to split the data and rerun the models, but we note that there are very few data points.

```
tmp_short <- creole_stability %>% filter(duration <= 250)
tmp_long <- creole_stability %>% filter(duration > 250)
```

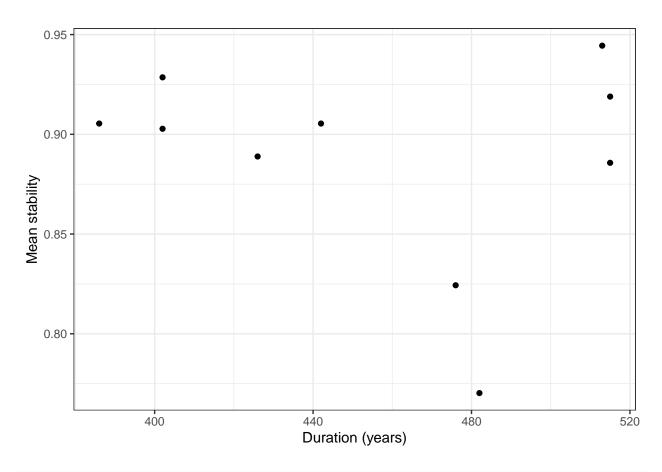

```
ggplot(tmp_short, aes(x = duration, y = MeanStability)) +
  geom_point() +
  xlab("Duration (years)") +
  ylab("Mean stability")
```

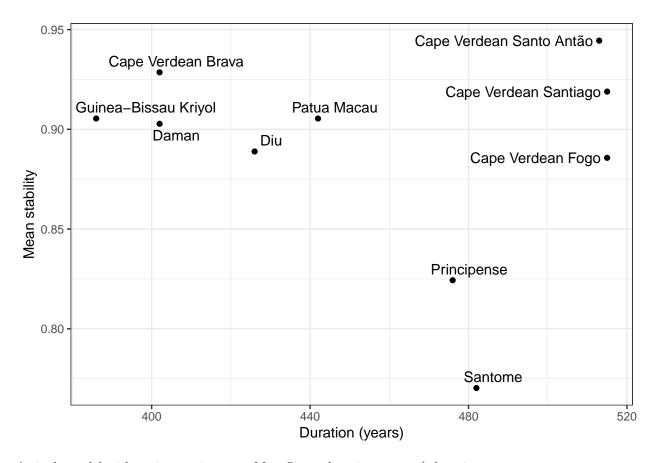

```
ggplot(tmp_short, aes(x = duration, y = MeanStability)) +
  geom_point() +
  geom_text_repel(aes(label = tmp_short$Language)) +
  xlab("Duration (years)") +
  ylab("Mean stability")
```

```
ggplot(tmp_long, aes(x = duration, y = MeanStability)) +
geom_point() +
xlab("Duration (years)") +
ylab("Mean stability")
```

```
ggplot(tmp_long, aes(x = duration, y = MeanStability)) +
geom_point() +
geom_text_repel(aes(label = tmp_long$Language)) +
xlab("Duration (years)") +
ylab("Mean stability")
```

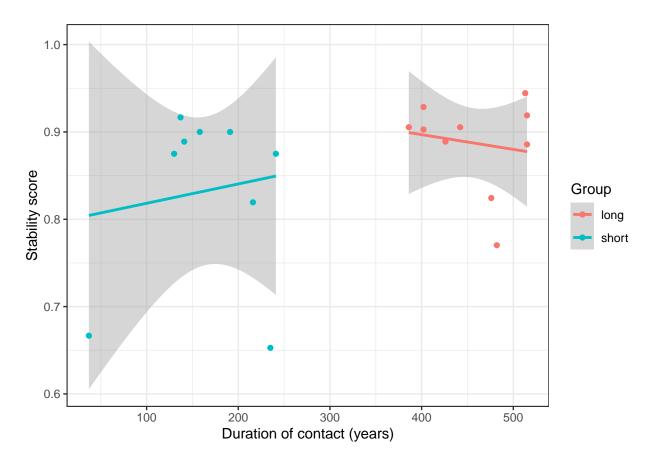

A single model with an interaction term MeanSim ~ duration, group * duration.

```
msd <- lm(MeanStability ~ duration + duration_group * duration, data = creole_stability)
summary(msd)</pre>
```

```

  geom_smooth(method = "lm") +
  geom_point() +
  xlab("Duration of contact (years)") +
  ylab("Stability score") +
  labs(color = "Group")
```

The variability in the two groups is very different. The direction of the effect is interesting: shorter durations yield more stability more consistently. Over time, the variability in mean stability increases. Time is "destabilizing the pattern of stability".

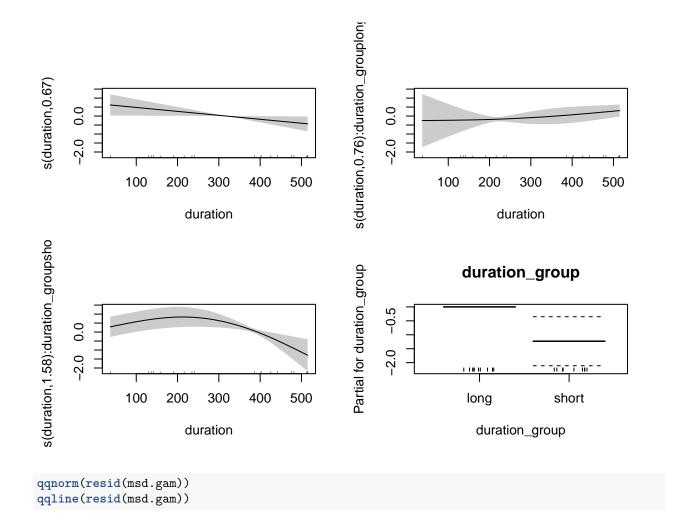

But it looks like you might have something tastier on your hands. The creoles appear to be bouncing back toward the lexifier over time (based on the duration findings; but perhaps I misunderstand).

And we can also increase the number of observations by running the analysis at the segment level, rather than on mean stability.

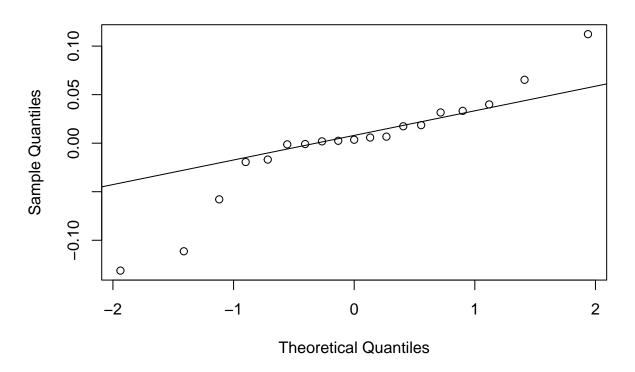

Exploratory analysis with a generalized additive model (GAM).

Main effect of duration

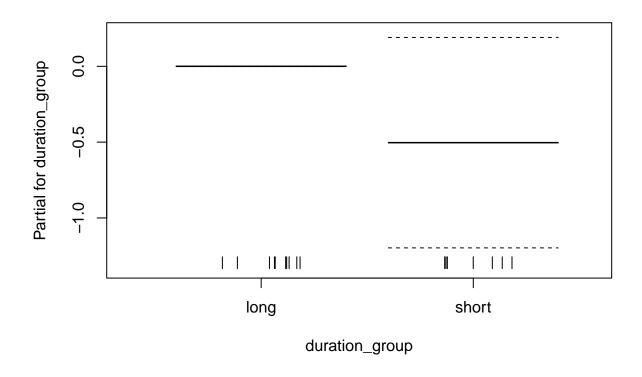

Long-term influence

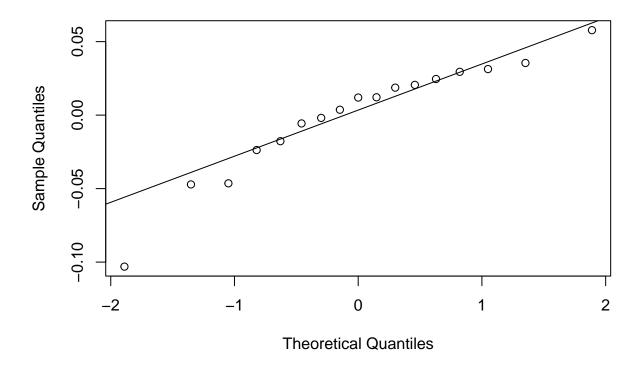

Short-term influence

```
# checking out the model performance
qqnorm(resid(msd.gam.trimmed))
qqline(resid(msd.gam.trimmed)) # meh
```

Normal Q-Q Plot

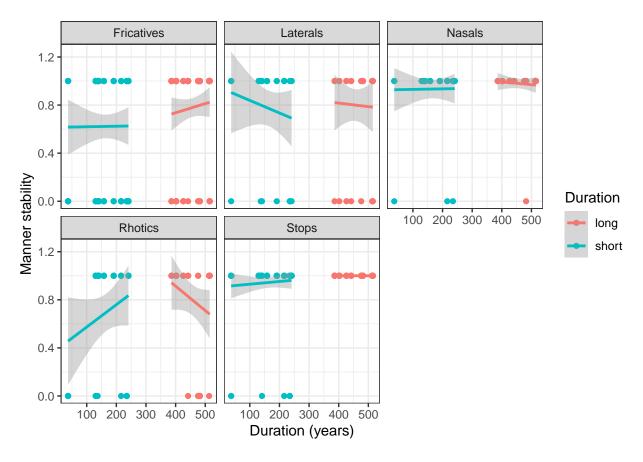

Removing the two creoles with the lowest scores produces significant effects. This doesn't seem very reliable though, especially given the small sample size. Also, the pattern is strange: a negative trend of duration for long-term influence and a positive one for short-term influence? Note that the model detected a mean difference between duration groups, with the short group having (slightly) lower mean stability. This appears to be the case – but again – we have so few observations.

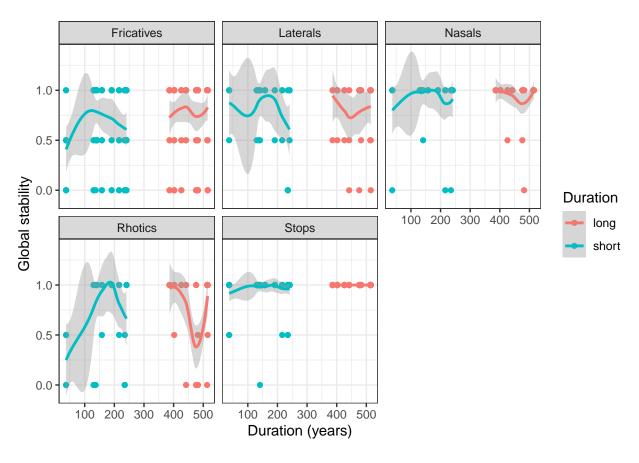

2.3 Duration effects on the segment level

Does duration affect the stability values of specific segments or segment classes?

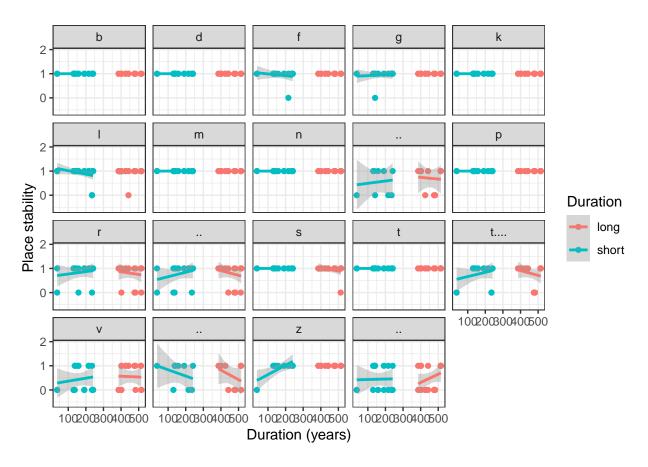

```
ggplot(database, aes(duration, MannerStability, colour = duration_group)) +

```

The Jaccard distance values were then manually extracted into a new table, so we could visualize those values according to the relevant language in contact (jaccard_results.csv). Then, we created a new table which summaries those results for creoles and joins their stability values, so we can assess if there is or there is not a correlation between the jaccard distances and the overall stability os creoles.

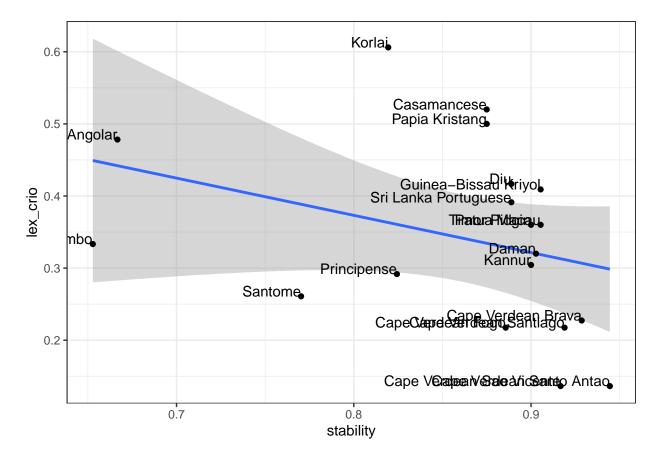

```
df_cor <- read.csv("jaccard_summary.csv")</pre>
```

3 Consonant stability

Which segments are the most stable across creoles in the language sample? We calculate stability of place and manner for each phoneme.

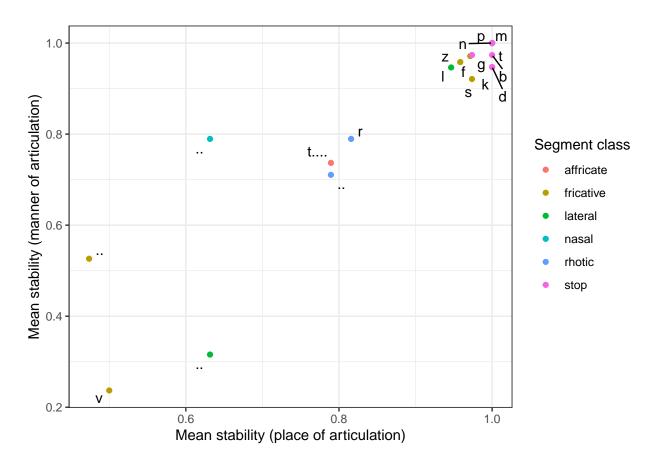

```
place_results <- database %>%
    group_by(LexifierPhoneme) %>%
    summarize(mplace = mean(PlaceStability, na.rm = TRUE))
manner_results <- database %>%
    group_by(LexifierPhoneme) %>%
    summarize(mmanner = mean(MannerStability, na.rm = TRUE))

consonant_stability <- left_join(place_results, manner_results, by = "LexifierPhoneme")</pre>
```

```
class <- c("stop", "stop", "fricative", "stop", "stop", "lateral", "nasal", "nasal", "stop", "rhotic", "f
consonant_stability_class <- cbind(consonant_stability, class)</pre>
```

Next, we plot the results.

```
ggplot(consonant_stability, aes(y = mmanner, x = mplace)) +
geom_point(position = "dodge", aes(color = class)) +
geom_text_repel(aes(label = LexifierPhoneme), size = 4) +
xlab("Mean stability (place of articulation)") +
ylab("Mean stability (manner of articulation)") +
labs(color = "Segment class")
```

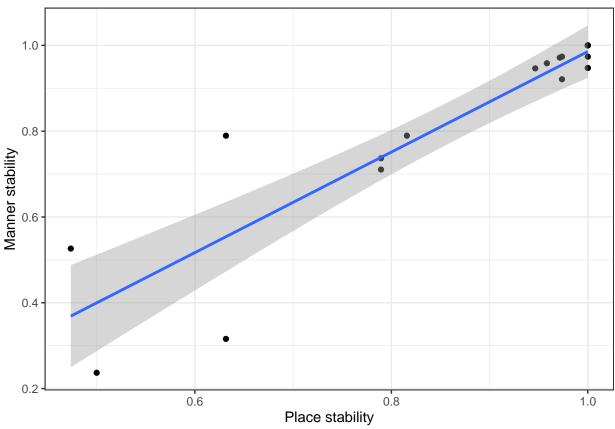

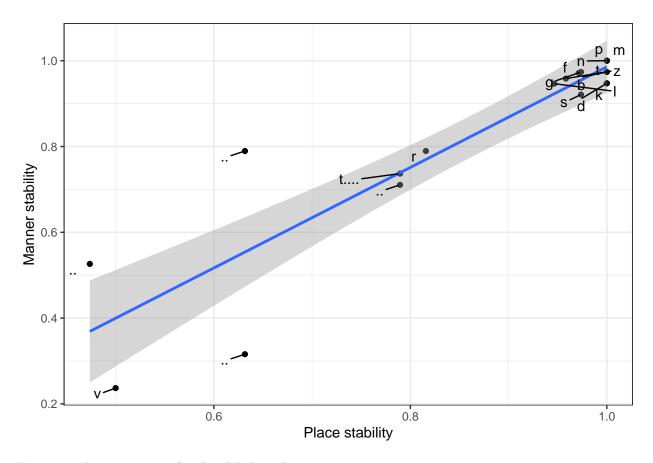

A linear model to assess the relationship between manner and place stability

```
lm_manner_place <- lm(mplace~mmanner, data=consonant_stability)
summary(lm_manner_place)</pre>
```

Here is an alternative view for the global results.

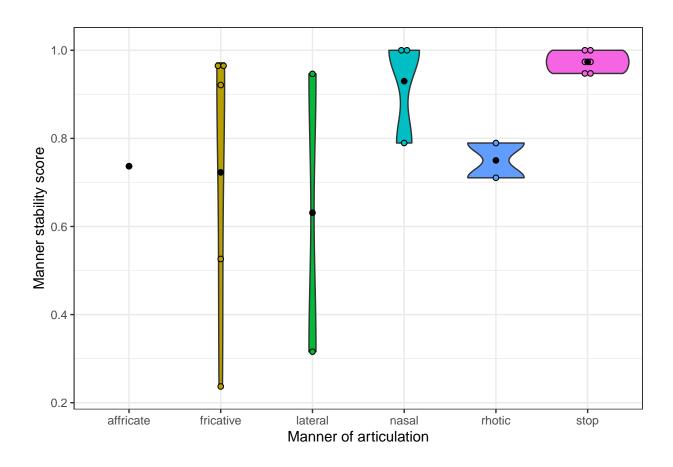

3.1 Manner stability

Check for class effects on the global stability of consonants

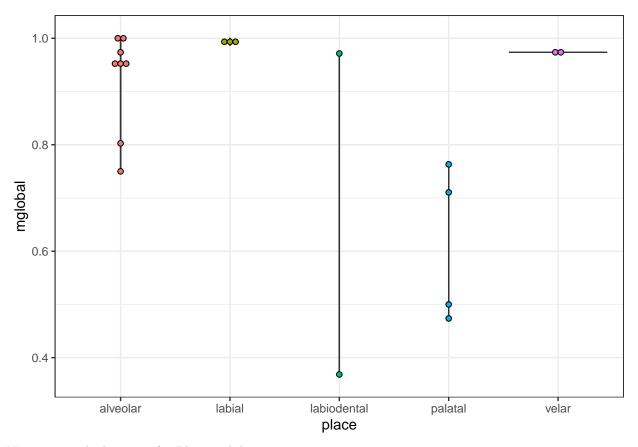

Now, just plotting the relation manner to manner

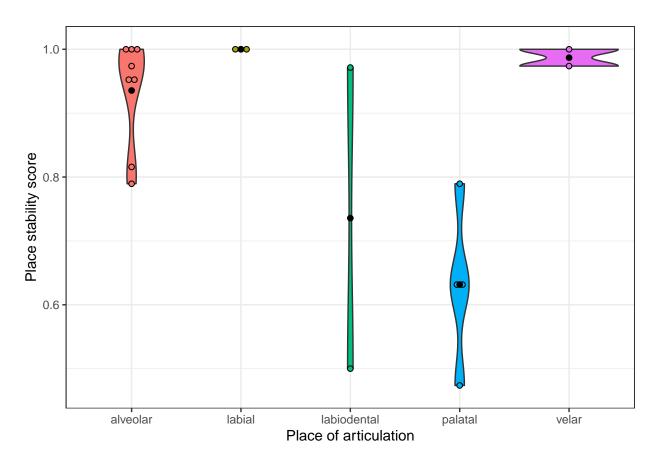

3.2 Place stability

Check place effects on the global stability of the consonants

```
place <- c("labial", "alveolar", "labiodental", "velar", "velar", "alveolar", "labial", "labial", "alveolar", "labial", "labial", "alveolar", "labial", "labial", "alveolar", "labial", "alveolar", "labial", "alveolar", "labial", "alveolar", "labial", "labial", "alveolar", "labial", "labial", "alveolar", "labial", "labial", "alveolar", "labial", "alveolar", "labial", "alveolar", "labial", "alveolar", "labial", "alveolar", "labial", "alveolar", "
```

Now, just with the mean for Place stability

Calculate the stability of the segments.

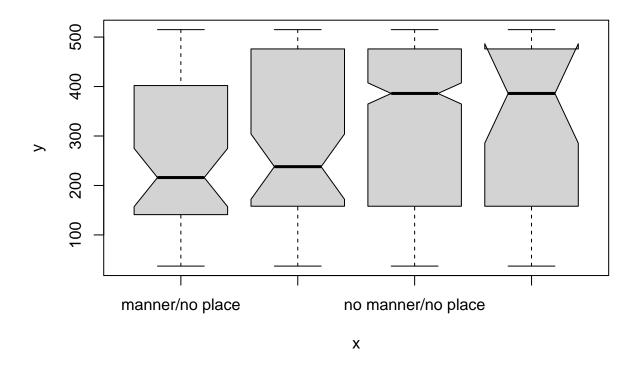

```
\# qplot(x = duration, y = MeanStability, data = consonant_global_stability, color = duration_group) + \\ \# qeom\_smooth(method = "lm")
```

And we can also increase the number of observations in duration regression by running the analysis at the segment level, rather than on mean stability.

```
# Factorizing
mod.db <- database %>%
    as.data.frame() %>%
    mutate(
        categorical_stability = as.factor(categorical_stability),
        Lexifier = as.factor(Lexifier),
        CreolePhoneme = as.factor(CreolePhoneme),
        Language = as.factor(Language)
    )

# Remove singletons/doubletons
# goodies = names(table(mod.db$CreolePhoneme)>2)

# mod.db = mod.db %>%
# filter(CreolePhoneme %in% goodies)
```

Hugely skewed in favor of no manner/place (10x as frequent as the next most frequent level; this could cause problems for the models).

```
table(mod.db$categorical_stability)
##

Some indication that place stability is more often associated with shorter periods of influence.

Numerically, the manner/place category has 50% of its observations in the longest duration from the sample. At the same time, no manner/no place is associated with the shortest duration.

3.3 Word position

Next we ask, does word position influence stability?

First, data preparation.

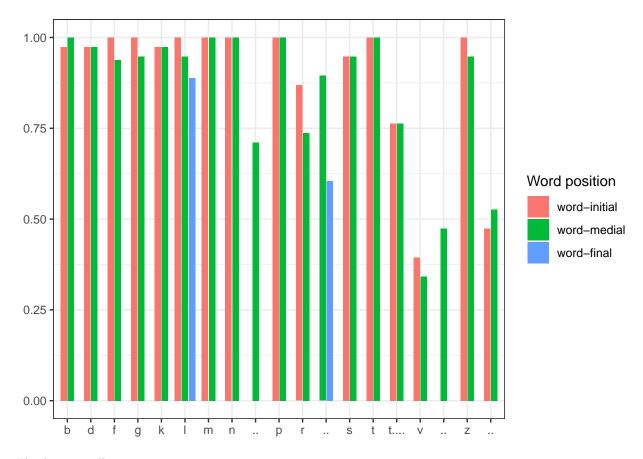

```
data_by_position <- database %>%
   dplyr::select(Position, LexifierPhoneme, PlaceStability, MannerStability) %>%
   mutate(Position = tolower(Position))

data_by_position$PlaceStability <- as.numeric(data_by_position$PlaceStability)

data_by_position$MannerStability <- as.numeric(data_by_position$MannerStability)</pre>
```

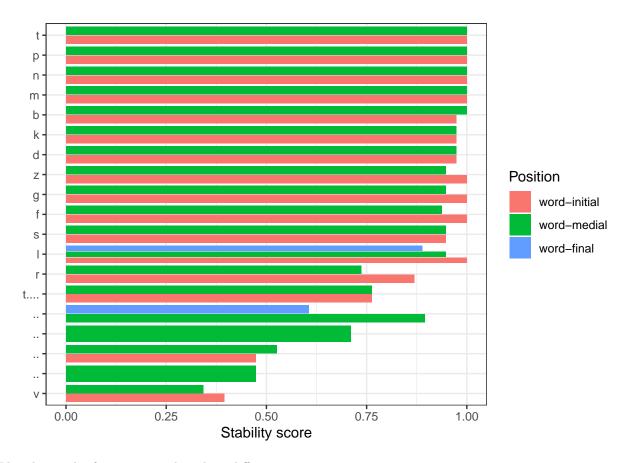

Next, calculate stability for each segment according to its word position.

And plot the results for all segments.

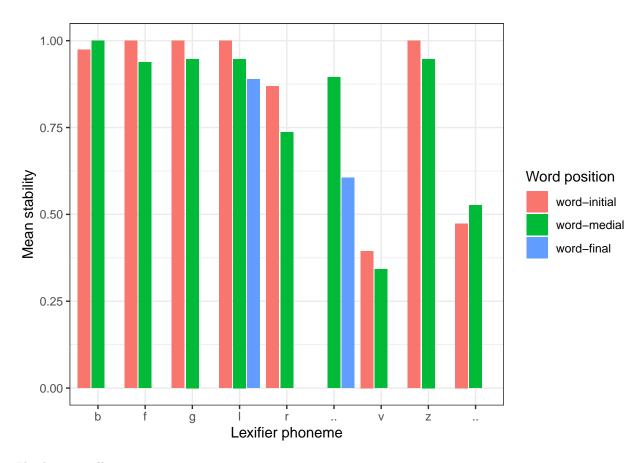

Flip horizontally.

```
ggplot(position_results) +
  geom_bar(
  aes(
    x = m,
    y = reorder(LexifierPhoneme, m),
    fill = Position
  ),
  stat = "identity",
  show.legend = TRUE,
  position = "dodge2"
  ) +
  labs(x = "Stability score", y = "", fill = "Position")
```

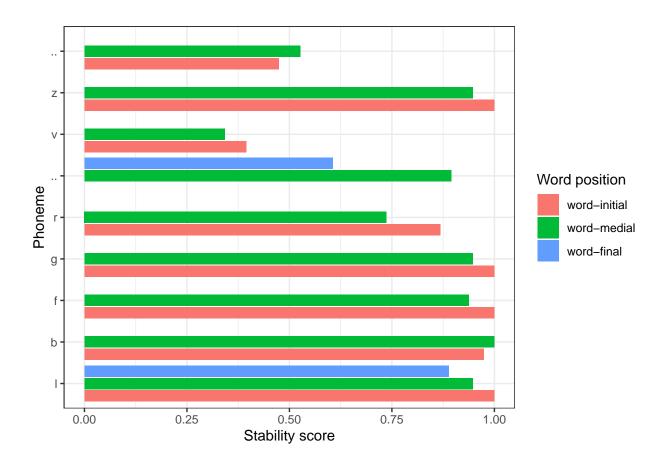

Plot the results for segments that show differences.

```
position_results1 <- position_results %>%
 pivot_wider(names_from = Position, values_from = m)
different_position <- subset(position_results1, position_results1$`word-initial`</pre>
                             != position_results1$`word-medial` |
                               position_results1$`word-final`
                             != position_results1$`word-medial`)
different_position_results <- different_position %>%
 pivot_longer(c(`word-initial`, `word-medial`, `word-final`),
               names_to = "Position", values_to = "m")
different_position_results Position <- factor(different_position_results Position,
                                              levels = c("word-initial",
                                                          "word-medial",
                                                          "word-final"))
ggplot(
 different_position_results,
  aes(x = LexifierPhoneme, y = m, fill = Position)
) +
  geom_col(position = position_dodge2(width = 0.9, preserve = "single")) +
  labs(x = "Lexifier phoneme", y = "Mean stability", fill = "Word position")
```

Flip horizontally.

```
ggplot(different_position_results) +
  geom_bar(
    aes(
        x = m,
        y = reorder(LexifierPhoneme, m),
        fill = Position
    ),
    stat = "identity",
    show.legend = TRUE,
    position = "dodge2"
    ) +
    labs(x = "Stability score", y = "Phoneme", fill = "Word position")
```

3.4 Typological frequency and borrowability

First, we turn the data into ordinal.

Ordinal data was generated by ranking the percentage values of stability, borrowability and typological frequency from 1 to 19. Duplicate values summed and averaged in the ranking.

1) Cross linguistic frequency

```

```

Which languages have bigger inventories?

```
stat = "identity",
show.legend = TRUE,
position = "dodge2") + coord_flip()
```

Violin plot: the majority of creoles have larger consonant inventories than Portuguese.

Consonant frequency in all languages involved

Count frequent consonants

```
total <- rowSums(cons_count)

cons_freq <- data.frame(cbind(df_total_inv$Phoneme, total))

cons_freq <- transform(cons_freq, total = as.numeric(total))

colnames(cons_freq)[1] <- "LexifierPhoneme"</pre>
```

Is there a relationship between this frequency and the stability values?

Subset: Portuguese consonants only

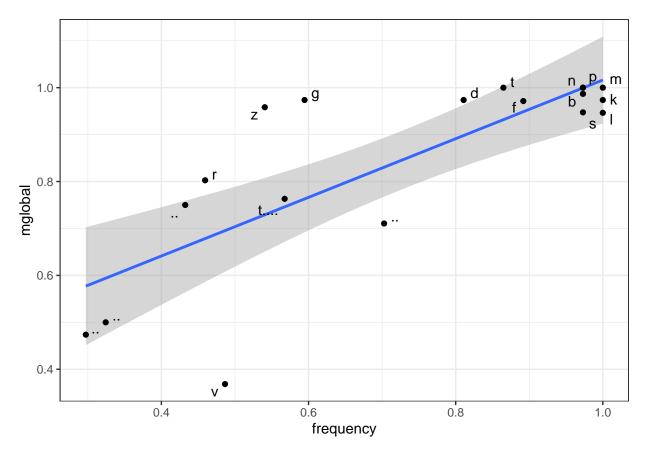

First dataset: relative frequency values

```
cons_freq_rel <- cons_freq_pt %>% mutate(frequency = total/37)
```

Second dataset:stability values

```
consonant_global_stability <- read.csv("consonant_global_stability.csv")</pre>
Merge datasets
cor_freq_sta <- left_join(consonant_global_stability, cons_freq_rel, by='LexifierPhoneme')</pre>

There relationship between stability and frequency across all languages involved. But does it make sense? We are measuring the consonants in all categories and the present of the lexifier and the creoles may influence the results. Perhaps, we should try to subset and measure the frequency across substrates only, but I think that this procedure would just increase the lack of correlation.

Is there a relationship between consonant stability and their presence in the inventories of the substrate languages?

Data preparation (substrates only)

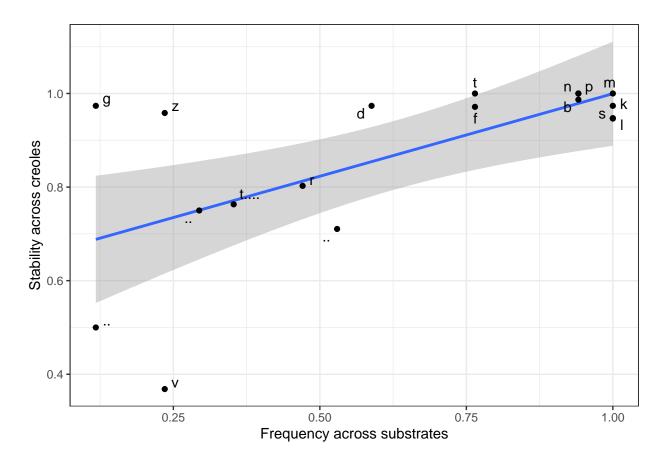

```
inv_subs <- inv %>% subset(Category == 'substrate') %>% dplyr::select(Language, Phoneme) %>% mutate(n
inv_subs_long <- inv_subs %>% pivot_wider(names_from = Language, values_from = newcol, values_fill = 0)
inv_subs_long <- inv_subs_long %>% mutate_at(c(2:18), as.numeric)
head(inv_subs_long)
```

```

        Min
                  1Q
                       Median
                                     30
## -0.63261 -0.13468 0.05119 0.18579 0.28145
##
## Coefficients:
               Estimate Std. Error t value Pr(>|t|)
## (Intercept) -0.3825
                            0.3091 -1.238 0.23374
                                      3.338 0.00418 **
## mglobal
                 1.1634
                             0.3486
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
## Residual standard error: 0.2672 on 16 degrees of freedom
     (1 observation deleted due to missingness)
## Multiple R-squared: 0.4105, Adjusted R-squared: 0.3736
## F-statistic: 11.14 on 1 and 16 DF, p-value: 0.004175
```

Plot the results

```
subsfreq_sta_cor <- ggplot(subs_sta, aes(x = frequency, y = mglobal, label = LexifierPhoneme)) +
    geom_smooth(method = "lm") +
    geom_point() +
    xlab("Frequency across substrates") + ylab("Stability across creoles") # +
    # geom_text(aes(label=V1), hjust=3, vjust=0)</pre>
subsfreq_sta_cor + geom_text_repel(aes(label=LexifierPhoneme))
```

When we consider the correlation between the consonant stability in creoles and the frequency of these consonants in the substrates only, we find that there is a weaker correlation (if we compare with the results above). However, this correlation is statistically significant (p-value: 0.004). Nothing the outliers which are normally voiced consonants.

Typological frequency vs. Substrate frequency

Typological frequency data, extrated from PHOIBLE

```
typ_freq <- read.csv("typ_freq.csv")</pre>
```

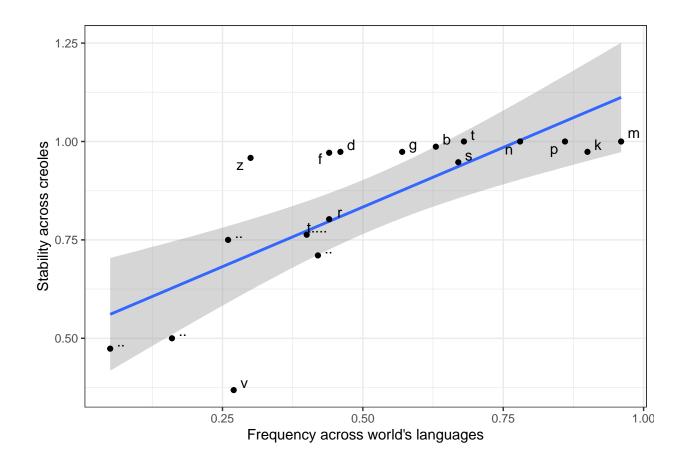

Merge datasets

```
#consonant_global_stability <- read.csv("consonant_global_stability.csv")

typ_sta <- left_join(typ_freq, consonant_global_stability, by='LexifierPhoneme')</pre>
```

Results of a simple regression

```
typ_sta_lm <- lm(TypologicalFreq ~ mglobal, data=typ_sta)</pre>
